Preface

This report describes Alaska's projected future population based on historical population data and rates of fertility, mortality, and migration. These projections provide planners and policymakers with possible outcomes of a series of demographic events.

It is important to note that Alaska is susceptible to many unpredictable events and that no demographer or economist can foresee the future. Our projections are based on past and hypothetical future population trends.

Special acknowledgment goes to the Alaska Department of Health for providing essential information for these projections.

We welcome comments or suggestions on the content or format of this publication. Many of the most requested statistics in this document are also available on the Research and Analysis website at laborstats.alaska.gov.

Send requests for demographic projections information to:

100 Appendix A: Technical Notes
102 Appendix B: Technical References

Introduction and Overview

These population projections cover 2025 through 2055 for Alaska by age and sex as well as for Alaska Native and region, borough, and census area populations.

Population projections are distinct from population estimates in that estimates use current and historical data to make statements about the present and past population, while projections use expected or extrapolated data to make statements about future populations. Though projections are uncertain, they're based on reasoned assumptions and are an important tool for planners and policy makers.

To create this set of projections, we used a cohort-component technique, separating the population of males and females into age groups and aging them forward in time. We then added projected births and in-migrants and subtracted projected deaths and out-migrants. See Appendix A for more details.

These projections are for residents as defined by the U.S. Census Bureau. The Census Bureau uses the concept of "usual residence" (self-reported) to determine where people are counted.

Statewide Projections

Alaska's population is projected to decrease from 738,737 in 2025 to 724,936 in 2055. The population is projected to grow for the first 10 years, but as the population ages, annual natural growth is expected to slow, leading to population losses due to net migration.

Alaska's population aged 65 or older is expected to grow by 16 percent over the projection period. However, the population under 65 is projected to decline. Losses through net migration are projected to shrink the population aged 20 to 64 (-2 percent) and lower birth rates are projected to decrease the 0 to 19 population (-12 percent).

Because growth is so uncertain, we created three scenarios for the statewide projections. We divided the population into single-year age groups by sex and projected forward one year at a time. We repeated this process three times, keeping the mortality and fertility projections the same but varying the net migration rate.

The middle projection for Alaska uses an annual net migration rate of -0.35 percent for the first year and -0.25 percent thereafter, the high scenario uses a net migration rate of 0.5 percent, and the low scenario uses a net migration rate of -1 percent.

Alaska Native Projections

The Alaska Native population, including Alaska Natives who report more than one race, is expected to continue to grow over the projection period, from 165,951 in 2025 to 172,182 in 2055. Like the state overall, the Alaska Native population's growth is expected to slow and eventually reverse as the population ages.

To create projections for the Alaska Native population, we divided the population into five-year age groups by sex, then projected forward in five-year intervals. We created projections for mortality, fertility, and migration rates based on recent time series data.

Region, Borough, and Census Area Projections

Alaska's regions, boroughs, and census areas have grown and are projected to continue growing at varying rates. Southwest will grow fastest.

For projections by borough and census area, we broke the populations into five-year age groups by sex and projected in five-year intervals using the cohort-component method. We created projections of mortality, fertility, and migration rates for each borough and census area based on recent time series data.

We projected each borough and census area population separately, with the sum of all borough and census area projections closely matching the statewide middle scenario projection at each step. We eliminated any discrepancies between the sum of the borough/census area projections and the statewide middle scenario projection with proportional fitting (described in Appendix A).

Section 1

Statewide Population Projections

As of July 1, 2025, Alaska's estimated population was 738,737.

Population change has four distinct processes, or components: fertility, mortality, in-migration, and out-migration. We used historical data on each of these components to create these projections.

This section begins with a brief description of Alaska's recent population background, then describes Alaska's mortality, fertility, and migration levels and their impacts on the projections. Finally, it presents the results and interpretation of the statewide projections.

Background

Since statehood in 1959, when the population was roughly 224,000, Alaska has grown at varying rates. As Figure 1.1 shows, both natural increase (the difference between births and deaths) and net migration (the difference between in-migration and out-migration) have played important roles. Since statehood, natural increase has provided Alaska with steady growth.

In- and out-migration have been far more uncertain components of this population change, as the numbers of people moving into and out of the state have varied greatly from year to year.

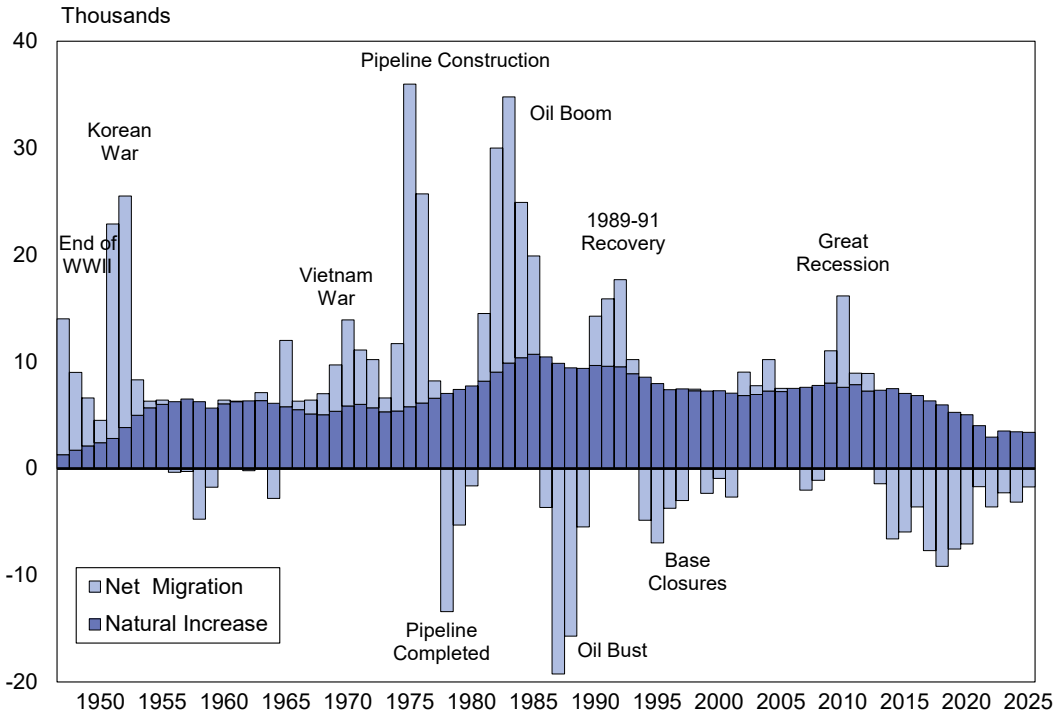

The discovery of oil in Prudhoe Bay in 1968 and the subsequent construction of the Trans-Alaska Oil Pipeline in the 1970s had a massive effect on Alaska's population, both immediately and in the following decades. Tens of thousands of workers and their dependents poured into the state for the construction of the pipeline, and many left at its completion.

In the years that followed, a huge number of migrants flowed into Alaska with new oil revenues and high oil prices, but many left when oil prices plunged in 1985.

These projections don't include events on the scale of the Trans-Alaska Oil Pipeline. Those do happen, however, and the oil discovery at Prudhoe Bay demonstrates that major economic events are always possible.

Cohort-Component Method

We created this set of population projections through a "cohort-component" technique. Under this approach, we separated the population into specified age groups by sex and aged them forward in time, adding projected births and in-migrants at each step while subtracting deaths and out-migrants.

Two of the distinct benefits of this approach are its careful disaggregation of the components of population change and its production of projections by age and sex.

To estimate the effects of mortality and fertility on population change, we applied distinct rates of mortality and fertility to each age-sex group as we aged them forward. To estimate the impact of migration, we applied the number of people resulting from annual ratios of in- and out-migration to age-by-sex profiles. We then added the calculated number of in-migrants to each respective age-sex group and subtracted the number of out-migrants from each group.[1]

Migration and Alternative Scenarios

Two values project migration for Alaska: the annual ratio of in-migrants (the number of in-migrants divided by Alaska's mid-year population) and the annual rate of out-migration (the number of out-migrants divided by the mid-year population). The difference between the in- and out-migration values is the net migration ratio, which is equal to the total number of in-migrants minus the total number of out-migrants, divided by the mid-year population.

Because uncertainty is a major factor in all population projections, and migration is the most uncertain component of population change, these projections include three scenarios with varying net migration ratios.

Figure 1.3 shows the dramatic swings of Alaska's net migration ratio in the past and the three net migration ratio paths we used for the different projection scenarios: -0.35 percent for the first year, then -0.25 percent middle scenario, 0.5 percent high scenario, and -1 percent low scenario.

For the last 13 years, Alaska's net migration has been negative. But multiple scenarios remain possible. Future employment will play a large role in migration, but changes in unemployment and labor force participation rates can play equally important parts. For the middle scenario, we extended the net migration losses of recent years for one year and used the 1995 to 2025 net migration annual average of -0.25 percent thereafter.

Although the differences between the scenarios we use may appear slight, they result in large differences in the projected population once each scenario is applied to our 30-year future projection period. While some states have had net migration consistently over 0.5 percent of their total population in recent decades — including Florida, Texas, Arizona, and South Carolina — no state's net migration has remained around -1 percent per year. Comparing 1990 to 2025 total population shows West Virginia was the only state with a loss — from 1.79 million to 1.77 million residents.

Mortality

Life expectancy at birth (or period life expectancy at birth) for a given year is the average number of years a person would live if he or she lived an entire life according to the respective year's age-specific mortality rates. Although life expectancy varies greatly from group to group within Alaska, Alaska's total life expectancy has historically been close to that of the United States as a whole.

As Table 1.2 shows, life expectancies in Alaska and the U.S. have been similar, with both declining from historical highs during the last decade. Since 2020, U.S. life expectancy has recovered and is now at historic levels while Alaska's has yet to rebound.

Despite Alaska's lagging life expectancy, we expect it

[1]Further description of the cohort-component method is provided in Preston, Heuveline, and Guillot (2001).

will follow a similar path to the nation's. To reflect this, we project Alaska mortality using a single path for change based on the U.S. Social Security Administration's projected future change in U.S. mortality.

The Social Security Administration projects that between 2020 and 2060, life expectancy will increase by 3.7 years for American men and 3.1 years for American women. Following fitted parameters based on this change, we expect life expectancy in Alaska to increase by 3.1 years for men and 2.1 years for women between 2025 and 2055.[2]

Fertility

The total fertility rate, or TFR, for a specific year is the number of children a woman would have if she followed that year's age-specific fertility rates throughout her lifetime. A TFR of approximately 2.1 (children per woman) is necessary for long term replacement-level natural increase.

Figure 1.2 displays historical estimates for Alaska's TFR. Alaska's TFR has been below replacement level since 2017, and this is not projected to change. Alaska's TFR (1.9) remains higher than that of the U.S. average (1.6) and provides steady growth from natural increase due to our young population.

Components of Change

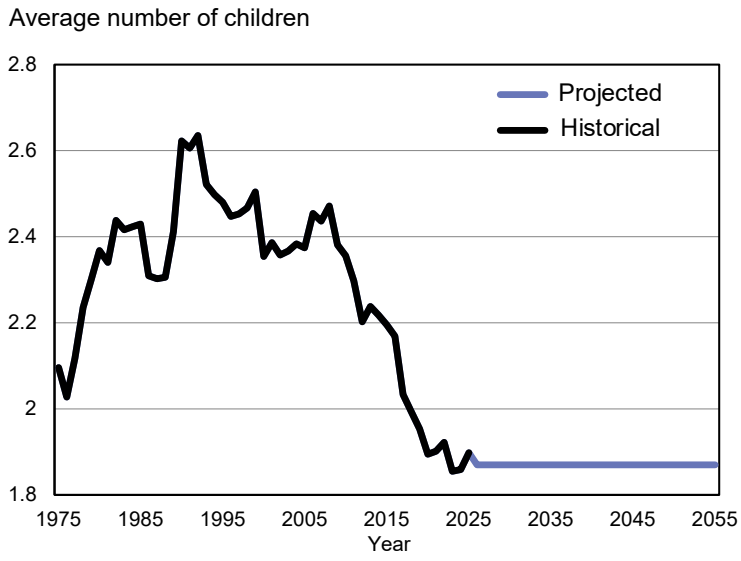

Table 1.3 provides projections of future levels of births, deaths, and net migration. The middle values are the expected births, deaths, and net migration. A net migration ratio of -0.35 percent is used for 2025 to 2026 and then -0.25 percent for the following years. The high and low projections of births, deaths, and net migration are the projected values if the net migration ratio for Alaska were fixed at 0.5 percent and -1 percent, respectively.

The middle and low scenarios project births to decline while the high projection shows increasing births. As the projection extends toward 2050, the difference in the projected number of births becomes much larger due to the accumulating difference in numbers of net-migrants.

[2]Appendix A provides the method for fitting the mortality parameters.

We expect the number of deaths in Alaska to increase greatly over the projection period. With the aging of the "baby boom" generation (those born in the high fertility period from 1946 to 1964), Alaska — like all states — will have a much larger elderly population than in the past, which will raise the annual number of deaths. Increasing differences in expected numbers of deaths are due to the varying levels of migration for each of the projection scenarios.

Table 1.3

Projected Annual Components Of Population Change for Alaska, 2025 to 2055

July 1 to June 30	Births			Deaths			Natural Increase			Net Migration

Alaska's Population Growth

Table 1.4 displays projections of the levels of population growth in Alaska from 2025 to 2055 and the outcome of different growth levels on the projected statewide population.

With the expected increase in deaths relative to births, the middle projection scenario shows Alaska beginning to lose population in 2035. The high and low scenario use hypothetical net migration rates to show how the population could grow or shrink if migration patterns change.

Figure 1.4 displays the different paths projected for Alaska's total population through 2055. With time, the different scenarios for Alaska's net migration cause differences between projected populations to increase greatly.

The middle projection produces a population for 2035 of 746,032, declining to 739,635 in 2045 and reaching 724,936 by 2055. The low scenario has the population dropping to 566,586 by 2055, and the high has it increasing to 925,038 people.

Future Population by Age and Sex

Tables 1.5 to 1.7 break down projections for Alaska's population by age and sex for each of the three scenarios. The median age of Alaska's population is projected to increase at a steady pace, rising from 37.1 in 2025 to 41.1 in 2055. The ratio of males per 100

Table 1.4

Population Projections for Alaska, 2025 to 2055

July 1 to June 30	End-of-Period Population			Population Change			Growth Rate (Percent)

females is expected to increase from 107.6 to 108.0.

Figures 1.8 through 1.11 show population pyramids for the middle scenario for 2025, 2035, 2045, and 2055.

Selected Age Groups

Figures 1.4 through 1.7 display the projected population for specified age groups. Alaska's population aged 0 to 19 is projected to decrease 12 percent, from 193,998 to 170,245 between 2025 and 2055.

Alaska's population aged 20 to 64 is an approximate representation of the working-age population. Alaska's 20-to-64-year-old population was 426,443 in 2025 and is projected to be 417,472 in 2055, a 2 percent decrease. This age group is highly impacted by migration rates causing large variations between projection scenarios. (See Figure 1.6.)

The population aged 65-plus is largely made up of retirees. While there is a great deal of uncertainty about future population for younger ages, which are substantially affected by shifts in fertility and migration rates, older people are less affected by these. Alaska's large cohort of aging baby boomers means strong growth in Alaska's senior population is very likely to continue.

Alaska's current population aged 65 or older is 118,296 and is projected to increase 15 percent by 2035, reaching 136,261 people. In 2046, millennials will begin aging into their senior years, reversing a 10-year decline in Alaska's senior population. By 2055, Alaska will have 16 percent more seniors (137,219).

Section 2

Alaska Native Population Projections

This section presents projections for the Alaska Native population by age and sex from 2025 through 2055. We created these projections based on estimates of the 2025 Alaska native population who are Native alone or in combination with one or more other races.[1]

While all Native Americans residing in Alaska are included in the Native projections, this group is almost entirely Alaska Native and will be referred to here as Alaska Native.

The Alaska Native population represents approximately 22 percent of the state's population. With high fertility and relatively low rates of migration, Alaska Native population growth is steady for much of the projected period. We based these projections on recent rates, however, which will vary over time.

Methodology

We divided the Alaska Native population into five-year age groups according to sex, then projected forward in five-year increments from the 2025 estimate of the Alaska Native race alone or in combination population, using the cohort-component method. We then added projected births, subtracted deaths, and subtracted net migration from the appropriate age-by-sex group.

[1]Appendix A further describes the Alaska Native estimates, the projection methods, and the methods for estimating age-by-sex-specific mortality, fertility, and migration.

Migration

Alaska Natives' rates of migration into and out of the state are low relative to Alaskans overall. After analyzing data from the 2000-2025 race alone or in combination estimates and Census counts, along with birth and death data, we set the annual net migration ratio at -0.5 percent of the population per year. The projections continue at this level of net migration through 2055.

Overall Population Change

The Alaska Native population is projected to grow steadily through 2050, from 165,951 in 2025 to 173,163 in 2050. Between 2050 and 2055, we project the Native population to decline slightly, to 172,182.

We also project Alaska Natives will slightly increase their share of Alaska's total population, from 22 percent in 2025 to 24 percent in 2055.

Annual births and deaths for Alaska Natives are both projected to rise, but we expect births to be consistently higher than deaths.

Aging

Aging will play an important role in population change for Alaska Natives over the projection period, as their median age is projected to rise from 30.3 to 35.9. The Alaska Native population aged 65-plus is projected to increase by 61 percent between 2025 and 2055, from 19,084 to 30,700.

Section 3

Region, Borough, and Census Area Projections

This section presents population projections for Alaska's economic regions, boroughs, and census areas by age and sex. Population projections for smaller areas have a much higher degree of uncertainty. Migration between boroughs, specific policy and economic factors, and unique historical events will all play important roles in determining actual population change.

Borough and census area projections are based on recent trends. Countless unforeseen factors could sway many populations dramatically.

The projected populations for each economic region, borough, and census area are presented by age and sex in five-year age groups from 2025 to 2055.

Methodology

For each borough and census area projection, we divided the population into age-by-sex groups and projected them forward in five-year increments from the 2025 estimate series using the cohort-component method.[1] We then added projected births and in-migrants and subtracted deaths and out-migrants from the appropriate age-by-sex group at each step. The projections for Alaska's economic regions are the sums of the boroughs and census areas they cover.

We projected each borough/census area population independently, using recent age-specific fertility rates to project births, recent and projected age-by-sex-specific mortality rates to project deaths, and recent annual migration data (adjusted for five-year intervals) and age-by-sex migration profiles to project migration.

We held constant the group quarters population (the population not living in households, such as those in prisons, barracks, or residential facilities) in age, sex, and size for the Aleutians East Borough, Aleutians West Census Area, and North Slope Borough.[2]

The sum of the borough and census area projections at each step matched closely to the middle statewide projection. Proportional fitting eliminated any discrepancies between the middle state projection and the sum of the borough and census area projections.

Births

Alaska's crude birth rate (the number of births per 1,000 people) for 2025-2026 is projected to be 12.2. With the overall aging of Alaska's population, this figure is projected to decline to approximately 10.9 by 2055.

Birth rates vary greatly across boroughs and census areas. The highest crude birth rates in 2025 were in Kusilvak Census Area (24.3), Bethel Census Area (19.2), and Northwest Arctic Borough (18.5).

The lowest birth rates for 2025 were found along the Aleutian chain and primarily in Southeast Alaska. In the Aleutians East Borough and Aleutians West Census Area, where much of the population lives in group quarters for fishing and fish processing, the crude birth rates were 2.0 and 4.0, respectively. Other areas with low birth rates included the Petersburg Borough (6.2), Hoonah-Angoon Census Area (6.7), Denali Borough (7.4), and City and Borough of Yakutat (7.9).

The rank-order of crude birth rates for boroughs and census areas probably will not change much over the projection period. While birth rates will change as the population composition shifts, places with relatively high birth rates will likely remain high and those with low rates will stay low.

Deaths

Alaska's crude death rate (the number of deaths per 1,000 people) in 2025 was 7.5. The greatest contributing factor was the ratio of senior citizens to the overall population.

Like crude birth rates, crude death rates vary among areas. In 2025, the highest rates were in the City and Borough of Wrangell (11.3), Copper River Census Area (11.0), Yukon-Koyukuk Census Area (10.4), and Hoonah-Angoon Census Area (10.3). The lowest rates were in the Aleutians West Census Area (2.6), City and Borough of Yakutat (3.2), Aleutians East Borough (4.3), and Municipality of Skagway (4.4).

As Alaska's population ages over the projection period, crude death rates will likely increase in all boroughs and census areas.

[1]Further description of the cohort-component method is provided in Preston, Heuveline, and Guillot (2001).

[2]Appendix A further describes the methods for estimating age-specific mortality, fertility, and migration rates.

Migration

As with statewide migration, migration into and out of Alaska's boroughs and census areas represents a highly unstable component of population change. We used two values to project migration for Alaska's boroughs and census areas: the annual net migration ratio (net migration divided by the borough or census area's mid-year population) and the annual out-migration rate (the number of out-migrants divided by the borough or census area's mid-year population). We estimated out-migration and net migration levels for each borough/census area based on 2015 to 2025 data to project migration through 2055.

We distributed the migrants proportionally using age-by-sex migration profiles to estimate the number of migrants for each specific age-by-sex group. The migration levels applied for the projection period reflect those from recent history.

The Matanuska-Susitna Borough is the only area we project to have strong positive net migration through the entire projection period.

Rural boroughs and census areas with high fertility rates, such as the Bethel and Kusilvak census areas, are projected to lose population through net migration but continue to grow overall through natural increase.

Overall Results

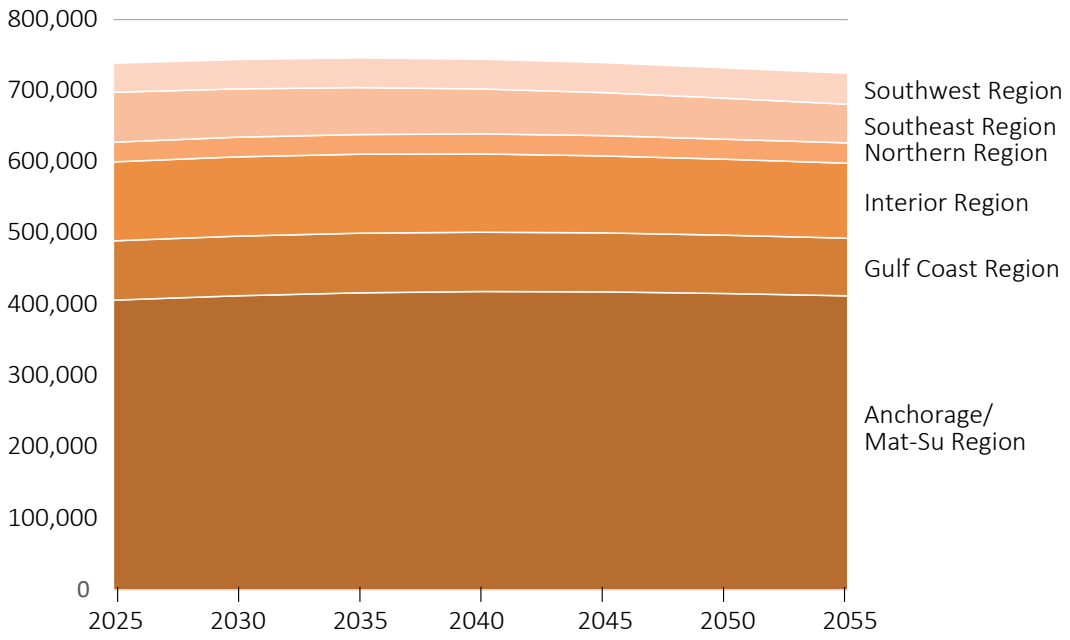

As shown in Figure 3.1, we project the strongest growth for the Southwest Region, which will continue growing through high fertility rates despite substantial net losses from migration.

The continuation of recent population trends for Alaska's economic regions will lead to growth for some regions and declines for others. The Southwest, Northern, and Anchorage\Mat-Su regions are all projected to grow while the Gulf Coast, Interior, and Southeast regions decline. Despite the regions' differing growth patterns, we do not expect the population rank-ordering of the regions to change.

The boroughs/census areas with the highest levels of projected average annual growth over the period include the Mat-Su Borough (1.2 percent), North Slope Borough (0.7 percent), Kusilvak Census Area (0.7 percent), and Southeast Fairbanks Census Area (0.5 percent). The boroughs/census areas with the most projected loss are the Haines Borough (-1.1 percent), City and Borough of Wrangell (-1.0 percent), and City and Borough of Sitka (-0.9 percent).

Projected Components of Population Change, 2025-2055

	Average Annual				
	Births	Deaths	Net Migration	Population Change	Growth Rate
2025-2030	16	11	-11	-6	-0.4%
2030-2035	15	12	-10	-7	-0.5%
2035-2040	15	12	-10	-7	-0.6%
2040-2045	15	13	-8	-6	-0.5%
2045-2050	14	13	-9	-8	-0.7%
2050-2055	13	12	-8	-7	-0.6%

Note: Average annual numbers are rounded to whole numbers.

Appendix A

Technical Notes

This technical appendix explains the methods used to produce the 2025 to 2055 Alaska population projections. It first presents methods we used to estimate and project statewide mortality, fertility, and migration rates, then describes how we applied these estimates with a cohort-component model.

Next, this appendix discusses how we projected each borough and census area's mortality, fertility, and migration rates, and how we applied these rates with a cohort-component model.

Finally, it explains the race "alone or in combination" estimates and the methods for projecting Alaska Native births, deaths, migration, and population. All computations use the R statistical package, SPSS, and Microsoft Excel.

Statewide Mortality

We used the Brass relational logit model for mortality (Preston, Heuveline, and Guillot, 2001) to project mortality rates. Projected mortality rates are based on a linear interpolation of Brass coefficients calculated from Social Security life tables for the United States for 2020 and 2060 (Bell and Miller, 2005), by sex. We then applied the interpolated coefficients to a 2023-2025 Alaska life table, created using Alaska vital statistics data, producing age-specific mortality rates for 2025 through 2055 for males and females.

Statewide Fertility

To project fertility, we used 2023 to 2025 Alaska vital statistics data to create a proportional age-specific fertility profile. We then multiplied the profile by a total fertility rate (sum of age-specific fertility rates) of 1.9 and held it constant across the projection period.

Statewide Migration

Two values project migration for Alaska: the annual ratio of in-migrants (the number of in-migrants divided by Alaska's mid-year population), and the annual rate of out-migration (the number of out-migrants divided by the mid-year population).

The difference between the in- and out-migration values is the net migration ratio, which is the total number of in-migrants minus the total number of out-migrants, divided by the mid-year population.

To make the different net migration scenarios, we adjusted both the in-migration ratio and the out-migration rate. For the middle scenario, we used an annual rate of -0.35 percent for the first year, based on the last few years of migration losses, and -0.25 percent – in line with Alaska's long term, 1995 to 2025 level of net migration – thereafter. We set the in-migration ratio to 5.65 percent and the out-migration rate to 6 percent for the first year and set the in-migration ratio to 5.75 percent and the out-migration rate to 6 percent for subsequent year.

For the high scenario, which has a 0.5 percent net migration ratio, we set the in-migration ratio to 6 percent and the out-migration rate to 5.5 percent. For the low scenario, which has a -1 percent net migration ratio, we set the in-migration ratio to 5 percent and the out-migration rate to 6 percent.

We then assigned the overall numbers of in- and out-migrants to the proper age-by-sex categories based on share profiles for in- and out-migration. We estimated migration share profiles by subtracting births and deaths from age-specific Alaska Permanent Fund Dividend applicant nonmatches, or people who were absent from one year of two consecutive annual Permanent Fund applicant files.

Statewide Projection Model

Once we calculated the necessary components, we applied them with a cohort-component projection model (Preston, Heuveline, and Guillot, 2001). For this model, we used Leslie Matrices to project natural increase — the effects of births and deaths on a population — while subtracting projected out-migrants and adding in-migrants at each step. We ran this model three times with the different migration scenarios to produce the middle, high, and low projections.

Borough/Census Area Mortality

GGiven the very small populations of Alaska boroughs and census areas, it wasn't practical to create age-by-sex specific mortality rates at the sub-state level. Rather than apply the statewide levels of mortality to each borough and census area, we decided to account for the distinct racial composition of each area and adjust the levels of mortality accordingly. We linearly interpolated levels of mortality between statewide Alaska Native (alone or in combination with one or more other races) and non-Native life tables based on the total proportion of Alaska Natives in each borough and census area.

The next step was to apply the Brass projection coefficients that were calculated for statewide mortality to the interpolated life tables. Applying the Brass coefficients yielded age-specific rates of mortality for 2025 through 2055, based on the U.S. Social Security Administration's projected change in U.S. mortality.

Borough/Census Area Fertility

We calculated age-specific fertility rates for each borough and census area using data from 2020 to 2025 with adjustments for group quarters populations (population not living in households) and held those rates constant through the projection period.

Borough/Census Area Migration

We estimated migration for each borough and census area using the net migration ratio and the out-migration rate of each area, based on 2015 to 2025 population estimates and Alaska Permanent Fund data, with adjustments for births, deaths, and groups quarters populations. Adding the net migration ratio to the out-migration rate produced the in-migration ratio (number of in-migrants divided by the mid-year population). We distributed migrants according to age-by-sex migration share profiles, previously estimated 2021 to 2025 Alaska Permanent Fund Dividend data.

The net migration ratios of boroughs and census areas are set to gradually converge toward the -0.25 net migration ratio of the middle state projection — sub-state net migration rates are halved over the projection horizon. This adjustment allows boroughs and census areas with positive net migration to continue gaining a reasonable number of in-migrants while keeping boroughs/census areas with high net migration losses from losing an unreasonable number of people to out-migration.

Borough/Census Area Projections

For borough and census area projections, we used the cohort-component method, like the state projection but with five-year steps – starting with 2025 – instead of single-year because of the smaller populations. We ran the model separately for each borough and census area, putting in each area's unique components of change.

To measure the closeness of the statewide and sum-of-borough population projections by age and sex, we calculated the "mean absolute percent error" (Smith, Tayman, and Swanson, 2001) across the ages and sexes and found less than 10 percent average errors among the age-by-sex groups for each projection step. We then proportionally adjusted the sub-state age-by-sex projections to match the middle state age-by-sex projection (Smith, Tayman, and Swanson, 2001).

Alaska Native Alone or In Combination

Beginning in 2000, the U.S. Census Bureau reformatted its race question, allowing people to select more than one race category. In previous population projections reports, we continued to provide Alaska Native and American Indian "bridged" data, which matched the pre-2000 categories. In 2015, we began producing projections for Alaska Native and American Indian alone or in combination with one or more other races.

Native Population Projections

To estimate age-by-sex-specific mortality rates for Alaska Natives, we used Alaska Native mortality data from the Alaska vital statistics for 2018 to 2025. We then applied the Brass coefficients from the U.S. Social Security Administration to project age-by-sex mortality through 2055. To project fertility, we used 2020 to 2025 Alaska vital statistics data to estimate a proportional age-specific fertility profile. We then multiplied the profile by a total fertility rate (sum of age-specific fertility rates) of 2.5 and held it constant across the projection period.

To estimate migration for Alaska Natives, we used the cohort-component method with the mortality and fertility age-by-sex profiles but no migration to project the 2020 estimated population to 2025. We compared the projected values with separate 2025 Alaska Native population estimates to find cohort change differences, estimating the amount of migration occurring within each age-by-sex interval. We further adjusted the overall level of migration based on Alaska Native population estimates for 2010-2025.

Then, as we did with the boroughs and census areas, we used the cohort-component method to project the Alaska Native population by age and sex in five-year steps from 2025 to 2055.
